Session Based

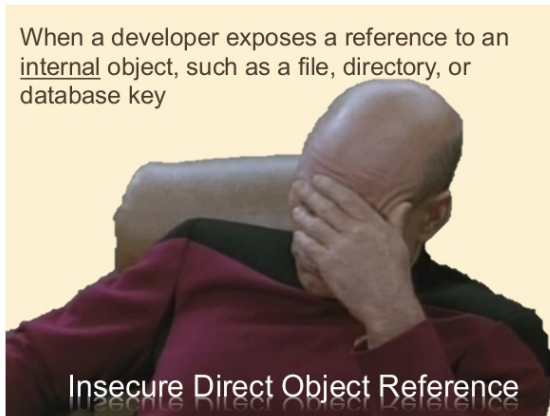

Check Authorization on every access

Solutions and Problems

## Summary

## What is *Insecure Direct Object References*

When a developer exposes a reference to an internal object, such as a file, directory, or database key

Insecure Direct Object Reference

# Threats

- ▶ **Threat Agents:** Any user who has only partial access to certain type of system data
- ▶ **Attacker's Approach:** Attacker, an authorized system user, simply changes a parameter value that directly refers to a system object to another object the user isn't authorized to use
- ▶ **Security Weakness:** Applications don't always verify the user is authorized for target objects

## Example: Code

### *Example Website:*

...

```
String query = "SELECT * FROM accts WHERE account = ?";  
PreparedStatement pstmt = connection.prepareStatement(query , ... );  
pstmt.setString( 1, request.getParameter("acct"));  
ResultSet results = pstmt.executeQuery();
```

...

2010 OWASP - CC-BY-SA

## Example: Attack

### Normal behavior

Example URL: `http://example.com/app/accountInfo?acct=myacct`

Result:

### Attack behavior

Example URL: `http://example.com/app/accountInfo?acct=notmyacct`

Result:

## Example: Attack

This URL:

`app/accountInfo?acct=myacct'; DROP accts; (5)`

How to prevent an Attack

Session Based

Check Authorization on every access

Solutions and Problems

Summary

# Session

- ▶ No *Direct Object Reference* has to be sent to the client, the references can be saved on the session
- ▶ In the case references are needed, they can differ from the server side data (i.e. database) and can be remapped on the server

# Authorization

- ▶ Every access is checked if the user is authorized to do that. Example: A random token can be created for each user which then is checked every time the user accesses the page

# Solutions and Problems

	<b>Advantage</b>	<b>Disadvantage</b>
<b>Session Based</b>	Only one authorization has to be done, access data for Database etc. is saved on the server and is not accessible by the attacker	A session uses a lot of memory for each user. For applications with a high number of users, a session for each client is not possible i.e. a non-session solution has to be implemented
<b>Authorization</b>	No Session is needed i.e. less memory is used and more users can access the application	Authorization is needed every time the user accesses data which is more complex to implement
